INTRODUCTION

Maternal thyroid function undergoes physiological changes during pregnancy and some of the most prevalent endocrine disorders seen in pregnancy are those related to thyroid dysfunction (Abalovich, 2007). Major, yet reversible changes in thyroid physiology are observed in pregnant women (Lazarus, 2011). The increased glomerular filtration rate which occurs in pregnancy can lead to increased losses of urinary iodine, resulting in iodine deficiency and eventually maternal goiter (Lazarus, 2011 and Idris, 2005). Thyroxine-binding globulin rises because of higher estrogen levels, and thyroid-stimulating hormone (TSH) levels fall as human chorionic gonadotropin concentration rises (Abalovich, 2007; Lazarus, 2011; Gallof, 2009). In sum, pregnancy-induced stress on the thyroid can lead to hypothyroidism in women with inadequate thyroidal iodine reserve or iodine deficiency. It is not until the end of the first trimester that the developing fetus starts synthesizing thyroid hormones, so it is dependent on the maternal thyroid hormone supply for the development of its organs and the central nervous system as well as general growth (Fitzpatrick, 2010 and Stagnaro-Green, 2011). Adverse outcomes including attention deficit and hyperactivity disorder have been observed in children born to mothers with hypothyroidism (Ghassabian et al., 2012). Normal thyroid hormones levels are key to maintaining a normal pregnancy until delivery (Choksi, 2003). Research points to an association between maternal hypothyroidism and higher risks of miscarriages, stillbirths, premature births, and pregnancy-induced hypertension (Montoro, 1997; Davis, 1988; Smalridge, 2001; Waterstrum, 1995 and Casey, 2005). Conversely, researchers have observed improved pregnancy outcomes in women who have been treated for hypothyroidism (Alexander, 2004). Elevated maternal thyroid hormone levels are also associated with adverse effects such as an increased risk of low birth weight, neonatal morbidity and mortality (Medici, 2013). Diagnosing women with thyroid dysfunction early in pregnancy allows early treatment and thus reduces the risk of adverse maternal and fetal outcomes (Ozdemir, 2013). While there is still some debate as to the most appropriate screening test for thyroid disorders in early pregnancy, most research suggests using TSH as the preliminary test, because this hormone is more sensitive indicator of thyroid function than FT4 and takes into consideration the log-linear TSH-FT4 relationship.
relationship (Ladenson, 2000; Dashe, 2005; Mandel, 2005). According to the Western literature, hypothyroidism in pregnancy is more prevalent than hyperthyroidism (2.5% vs. 0.2%, respectively) (LeBeau, 2006). There are only a few reports of the prevalence of pregnancy-related hypothyroidism in the Saudi context (Taha, 2011; Refaat, 2014). To provide more data on pregnancy-related thyroid disorders in Saudi Arabia, the current study aims to find the prevalence of hypothyroidism in Saudi women in their first trimester of pregnancy.

MATERIALS AND METHODS

This cross-sectional study was carried out at King Abdulaziz University Hospital (KAUH), the largest tertiary care center in Jeddah, Saudi Arabia. It included 154 first-trimester pregnant Saudi women attending the Obstetrics and Gynecology clinic between October and April 2015. Approval for the study was granted by the Biomedical Committee at the Faculty of Medicine, King Abdulaziz University. The sample size was based on the number of patients who met the inclusion criteria during the study period. Saudi women with singleton pregnancies, in the first trimester (6-13 weeks) and with a viable fetus were selected for inclusion. Women with a history of complicated multiple pregnancies, thyroid diseases, treatment with anti-thyroid drugs, family history of thyroid disorders, and medical conditions like hypertension, diabetes mellitus, renal and other autoimmune diseases were excluded from the study.

All the women were informed about the nature of the study and anyone who did not agree to participate was excluded. Socio demographic and medical information was obtained from each participant. Additionally, each subject underwent a complete physical examination including abdominal ultrasound to confirm gestational age and normality of pregnancy. At their first antenatal visit as part of routine laboratory workup, all participants were screened for thyroid function by measuring TSH levels. In the KAUH laboratory, TSH assay was performed using the electrochemiluminescence immunoassay (ECLIA) on Cobas e411 (Roche Diagnostics International Ltd, Switzerland) according to the manufacture protocol. The normal range according to the manufacturer for TSH was 0.27-4.20 μIU/mL and the detection sensitivity was 0.005 μIU/mL. The intra and interassay coefficient of variation for TSH was 1.4% and 3.4%, respectively.

Thyroid dysfunction was classified according to the guidelines set out by the American Thyroid Association (ATA) for diagnosing and managing thyroid disease during pregnancy [6].

- Hypothyroidism: TSH <2.5 μIU/mL
- Hyperthyroidism: TSH ≥0.03 μIU/mL

All subjects with abnormal TSH were requested to come for follow-up for further testing at the endocrine clinic at KAUH. A written informed consent was obtained from all participants who agreed to participate. Statistical presentation and analysis of the present data was conducted, using SPSS version 20.0 (SPSS Inc., Chicago, IL, USA). Continuous variables were analyzed as mean values ± standard deviation (SD). Percentages were calculated for categorical data.

RESULTS

Characteristics of the study population are given in Table 1. The mean maternal age of the study population ranged from 17-39 years with mean ± SD (24.4 ± 3.6). Sixty-three (40.9%) were nulliparous and 91 (59.09) were multiparous. The mean gestational age was 10.9 ± 2.0 weeks.

BMI: body mass index; GA: gestational age

Following trimester specific cutoffs of <2.5 μIU/mL for the first trimester as suggested by the ATA (Stagnaro-Green et al., 2011), we found 40.3% (n=62) of pregnant women to have hypothyroidism in the first trimester (Table 2). Hyperthyroidism was detected in one (0.6%) of the participants.

DISCUSSION

Thyroid disorders are common, and their prevalence rises in pregnancy (Karakosta, 2011 and Moleti, 2014). According to research by Casey et al., hypothyroidism during early pregnancy affects about 2.5% of pregnant women (Casey, 2005 and Casey, 2007). Similar figures were reported several studies (Männistö, 2009; Allan, 2000; Vaidya, 2007). These studies suggest that thyroid disorders are a common problem in pregnancy, in contrast with Gillett’s position that routine screening for thyroid function is not necessary in pregnant women, unless they have increased risk factors for thyroid disease (Gillett, 2004). This study aimed to evaluate thyroid function during the first trimester of pregnancy in Saudi women living in the Jeddah area. The major finding is that 40.3% of pregnant women attending KAUH have hypothyroidism. The prevalence of hypothyroidism in various countries has been reported in recent years (Qian, 2013; Habimana, 2014; Moreno-Reyes, 2013). Results of the present study are fairly consistent with recently reported figures from Saudi Arabia. In their hospital-based study of 936 pregnant women (12-30 weeks of gestation) in the Madinah region, Taha et al. observed hypothyroidism in 24.2% of the women (Taha, 2011).

Refaat (2014) (Refaat, 2014) reported hypothyroidism in 32.4% of 162 pregnant women (4-12 weeks of gestation) in Makkah. While somewhat higher, our results are consistent with these Saudi studies, suggesting a high prevalence of hypothyroidism in pregnant Saudi women. A large study carried out in Delhi, India reported a 14.3% prevalence of hypothyroidism in women in their first trimester (Dhanwal, 2013). A smaller scale study conducted in Hyderabad, India on 163 nonpregnant women with repeated pregnancy loss
The adverse outcomes associated with hypothyroidism in pregnancy tend to be seen when using a threshold of TSH levels greater than 2.5 mIU/L in the first trimester instead of a TSH reference range based on cutoff values derived from apparently euthyroid pregnant women. The ATA gives >2.5 µIU/ml as the recommended cutoff point for diagnosis of hypothyroidism during the first trimester. The high prevalence of gestational hypothyroidism in Saudi Arabia could be considered a major public health burden. Debate on the need for universal screening for hypothyroidism in early pregnancy is ongoing (Vila, 2013). In its recent guidelines, the ATA has withheld recommendations for the universal screening of pregnant women for hypothyroidism, citing lack of evidence (Vila, 2013). Hyperthyroidism has a much lower prevalence than hypothyroidism, occurring in only 0.5-2/1000 pregnancies (Price, 2001). If left untreated, pregnant women with hyperthyroidism have a significantly higher risk of obstetric complications including preeclampsia, preterm labor, low birth weight, fetal and perinatal mortality (Price, 2001). In the current study, newly diagnosed hyperthyroidism was seen in one participant (0.6%). This high prevalence of hyperthyroidism in our study population could be explained by a possible population-specific elevated sensitivity of the thyroid gland to thyrotrophic molecules like HCG, resulting in gestational toxicity. Price et al. reported similar differences between Asian and western Caucasian women in their study comparing thyroid function tests in both pregnant and non-pregnant women. The strong point of this study is that we have included only healthy pregnant women with no past or present history of thyroid diseases in this study and all samples were analyzed in one laboratory.

However, there are a few limitations of this study, which are the small sample size and being confined to only one hospital, which underestimate over all prevalence in the Saudi pregnant women population. This study suggests that hypothyroidism is more common in Saudi pregnant women in the Western Province of Saudi Arabia than it is in other countries. Given the negative maternal and fetal outcomes associated with maternal thyroid dysfunction, it is crucial that abnormal thyroid status be detected early and treatment started promptly. Therefore, screening pregnant women for maternal thyroid dysfunction as early as possible should be considered, particularly in a country like Saudi Arabia, which has a high prevalence of undiagnosed thyroid dysfunction. This study supports the use of TSH as a marker for pregnancy-induced hypothyroidism, but additional research on TSH during pregnancy without evidence of autoimmune thyroid disease is required to develop trimester-specific TSH reference ranges in the Saudi population. Further studies should be conducted to investigate the impact of gestational thyroid disorders in the Saudi population.

Acknowledgment
This research was supported by King Abdulaziz University Hospital, Jeddah, Saudi Arabia under the Research Reference No 235-16. Author is thankful to Dr. N. Al-Senani in Gynecology department at KAUH for sharing her pearls of wisdom during this research as well as for her comments that greatly improved the manuscript.
